The Theorem of Copeland and Erdős on Normal Numbers

Jordan Velich

University of Newcastle

February 3, 2015
**Definition**

A number $\alpha$ is **normal** with respect to the base $\beta$, provided each of the digits $0, 1, 2, \ldots, \beta - 1$ occurs with a limiting relative frequency of $1/\beta$, and each of the $\beta^k$ sequences of $k$ digits occurs with the relative frequency $1/\beta^k$.

**Definition**

The **natural density** of the subset $A \subset \mathbb{N}$, denoted $d(A)$, is defined as

$$d(A) = \lim_{x \to \infty} \frac{N(x)}{x}$$

where $N(x) := \#\{a : a \in A, a \leq x\}$.

**Example**

The natural density of the even numbers is $1/2$.

Theorem of Copeland and Erdős on Normal Numbers
Copeland-Erdős Theorem
Theorem (Copeland-Erdős, 1946)

If \(a_1, a_2, a_3, \ldots\) is an increasing sequence of integers such that for every \(\theta < 1\) the number of \(a_i\)'s up to \(N\) exceeds \(N^\theta\) provided \(N\) is sufficiently large, then the infinite decimal

\[
0.a_1a_2a_3\ldots
\]

is normal with respect to the base \(\beta\) in which these integers are expressed.
Lemma (Copeland-Erdős, 1946)

The number of integers up to \( N \) (\( N \) sufficiently large) which are not \((\varepsilon, k)\) normal with respect to a given base \( \beta \) is less than \( N^\delta \) where \( \delta = \delta(\varepsilon, k, \beta) < 1 \).

To understand this lemma, we must first be familiar with \((\varepsilon, k)\) normality:

Definition

A number \( \alpha \) (in the base \( \beta \)) is said to be \((\varepsilon, k)\) normal if any combination of \( k \) digits appears consecutively among the digits of \( \alpha \) with a relative frequency between \( \beta^{-k} - \varepsilon \) and \( \beta^{-k} + \varepsilon \).
Lemma (Copeland-Erdős, 1946)

The number of integers up to $N$ ($N$ sufficiently large) which are not $(\varepsilon, k)$ normal with respect to a given base $\beta$ is less than $N^{\delta}$ where $\delta = \delta(\varepsilon, k, \beta) < 1$.

To understand this lemma, we must first be familiar with $(\varepsilon, k)$ normality:

Definition

A number $\alpha$ (in the base $\beta$) is said to be $(\varepsilon, k)$ normal if any combination of $k$ digits appears consecutively among the digits of $\alpha$ with a relative frequency between $\beta^{-k} - \varepsilon$ and $\beta^{-k} + \varepsilon$. 
An Important Lemma

Lemma (Copeland-Erdős, 1946)

The number of integers up to \( N \) (\( N \) sufficiently large) which are not \((\varepsilon, k)\) normal with respect to a given base \( \beta \) is less than \( N^\delta \) where \( \delta = \delta(\varepsilon, k, \beta) < 1 \).

To understand this lemma, we must first be familiar with \((\varepsilon, k)\) normality:

Definition

A number \( \alpha \) (in the base \( \beta \)) is said to be \((\varepsilon, k)\) normal if any combination of \( k \) digits appears consecutively among the digits of \( \alpha \) with a relative frequency between \( \beta^{-k} - \varepsilon \) and \( \beta^{-k} + \varepsilon \).
Proof Of Lemma – \((\varepsilon, 1)\) normality

Let \(x\) be such that \(\beta^{x-1} \leq N < \beta^x\), where \(\beta^x\) refers to a number (base–\(\beta\)) consisting of \(x\) digits.

We introduce the notation \(\beta_j = (\beta - 1)^{x-j} \binom{x}{j}\), where \(\beta_j\) counts the number of numbers (up to \(N\)) which have a single digit, for instance 0, occurring a total of \(j\) times amongst their \(x\) digits.

Since a given base \(\beta\) has \(\beta\) digits, and since \(\beta_j\) counts the occurrences of only a single digit, there are at most

\[
\beta \left( \sum_{j < x(1-\varepsilon)/\beta} \beta_j + \sum_{j > x(1+\varepsilon)/\beta} \beta_j \right)
\]

numbers up to \(N\) which have less than \(x(1 - \varepsilon)/\beta\) or more than \(x(1 + \varepsilon)/\beta\) 0’s, 1’s, . . . , \((\beta - 1)\)’s.
Proof Of Lemma – \((\varepsilon, 1)\) normality

Let \(x\) be such that \(\beta^{x-1} \leq N < \beta^x\), where \(\beta^x\) refers to a number (base-\(\beta\)) consisting of \(x\) digits.

We introduce the notation \(\beta_j = (\beta - 1)^{x-j} \binom{x}{j}\), where \(\beta_j\) counts the number of numbers (up to \(N\)) which have a single digit, for instance 0, occurring a total of \(j\) times amongst their \(x\) digits.

Since a given base \(\beta\) has \(\beta\) digits, and since \(\beta_j\) counts the occurrences of only a single digit, there are at most

\[
\beta \left( \sum_{j < x(1-\varepsilon)/\beta} \beta_j + \sum_{j > x(1+\varepsilon)/\beta} \beta_j \right)
\]

numbers up to \(N\) which have less than \(x(1 - \varepsilon)/\beta\) or more than \(x(1 + \varepsilon)/\beta\) 0’s, 1’s, \ldots, \((\beta - 1)\)’s.
Proof Of Lemma – $(\varepsilon, 1)$ normality

Let $x$ be such that $\beta^{x-1} \leq N < \beta^x$, where $\beta^x$ refers to a number (base $- \beta$) consisting of $x$ digits.

We introduce the notation $\beta_j = (\beta - 1)^{x-j} \binom{x}{j}$, where $\beta_j$ counts the number of numbers (up to $N$) which have a single digit, for instance 0, occurring a total of $j$ times amongst their $x$ digits.

Since a given base $\beta$ has $\beta$ digits, and since $\beta_j$ counts the occurrences of only a single digit, there are at most

$$\beta \left( \sum_{j < x(1-\varepsilon) / \beta} \beta_j + \sum_{j > x(1+\varepsilon) / \beta} \beta_j \right)$$

numbers up to $N$ which have less than $x(1 - \varepsilon) / \beta$ or more than $x(1 + \varepsilon) / \beta$ 0’s, 1’s, $\ldots$, $\beta - 1$’s.
In order to prove the lemma for \((\varepsilon, 1)\) normality, we have to show that

\[
\beta \left( \sum_{j<x(1-\varepsilon)/\beta} \beta_j + \sum_{j>x(1+\varepsilon)/\beta} \beta_j \right) < N^\delta.
\]

We first require some intermediate inequalities.

We have from the properties of the binomial expansion:

\[
\sum_{j<x(1-\varepsilon)/\beta} \beta_j < (x + 1)\beta_{r_1}, \quad \sum_{j>x(1+\varepsilon)/\beta} \beta_j < (x + 1)\beta_{r_2}
\]

where

\[
r_1 = \lfloor (1 - \varepsilon)x/\beta \rfloor, \quad r_2 = \lfloor (1 + \varepsilon)x/\beta \rfloor
\]
Proof Of Lemma – \((\varepsilon, 1)\) normality

In order to prove the lemma for \((\varepsilon, 1)\) normality, we have to show that

\[
\beta \left( \sum_{j < x(1-\varepsilon)/\beta} \beta_j + \sum_{j > x(1+\varepsilon)/\beta} \beta_j \right) < N^\delta.
\]

We first require some intermediate inequalities.

We have from the properties of the binomial expansion:

\[
\sum_{j < x(1-\varepsilon)/\beta} \beta_j < (x + 1)\beta_{r_1}, \quad \sum_{j > x(1+\varepsilon)/\beta} \beta_j < (x + 1)\beta_{r_2}
\]

where

\[
\begin{align*}
r_1 &= \lfloor (1 - \varepsilon)x/\beta \rfloor, & r_2 &= \lfloor (1 + \varepsilon)x/\beta \rfloor
\end{align*}
\]
Proof Of Lemma – \((\varepsilon, 1)\) normality

In order to prove the lemma for \((\varepsilon, 1)\) normality, we have to show that

\[
\beta \left( \sum_{j < x(1-\varepsilon)/\beta} \beta_j + \sum_{j > x(1+\varepsilon)/\beta} \beta_j \right) < N^\delta.
\]

We first require some intermediate inequalities.

We have from the properties of the binomial expansion:

\[
\sum_{j < x(1-\varepsilon)/\beta} \beta_j < (x + 1)\beta_{r_1}, \quad \sum_{j > x(1+\varepsilon)/\beta} \beta_j < (x + 1)\beta_{r_2}
\]

where

\[
r_1 = \lfloor (1 - \varepsilon)x/\beta \rfloor, \quad r_2 = \lfloor (1 + \varepsilon)x/\beta \rfloor
\]
Proof Of Lemma – \((\varepsilon, 1)\) normality

By repeated application of the relation

\[
\frac{\beta_{j+1}}{\beta_j} = \frac{x - j}{j + 1}(\beta - 1)
\]

we obtain

\[
\beta_{r_1}^{\varepsilon x/2} < \beta^x, \quad \beta_{r_2}^{\varepsilon x/2} < \beta^x
\]

where

\[
\rho_1 = \frac{x - r_1}{r_1 + 1}(\beta - 1), \quad \rho_2 = \frac{x - r_2}{r_2 + 1}(\beta - 1)
\]

and where \(\rho_1, \rho_2 > 1\) for \(x\) sufficiently large.

It follows that

\[
\beta_{r_1} < \left(\rho_1^{-\varepsilon/2} \beta\right)^x, \quad \beta_{r_2} < \left(\rho_2^{-\varepsilon/2} \beta\right)^x
\]
Proof Of Lemma – \((\varepsilon, 1)\) normality

By repeated application of the relation

\[
\frac{\beta_{j+1}}{\beta_j} = \frac{x - j}{(j + 1)(\beta - 1)}
\]

we obtain

\[
\beta r_1 \rho_1^{\varepsilon x / 2} < \beta^x, \quad \beta r_2 \rho_2^{\varepsilon x / 2} < \beta^x
\]

where

\[
\rho_1 = \frac{x - r_1}{(r_1 + 1)(\beta - 1)}, \quad \rho_2 = \frac{x - r_2}{(r_2 + 1)(\beta - 1)}
\]

and where \(\rho_1, \rho_2 > 1\) for \(x\) sufficiently large.

It follows that

\[
\beta r_1 < \left( \frac{\rho_1^{-\varepsilon / 2}}{\beta} \right)^x, \quad \beta r_2 < \left( \frac{\rho_2^{-\varepsilon / 2}}{\beta} \right)^x
\]
Proof Of Lemma – \((\varepsilon, 1)\) normality

By repeated application of the relation

\[ \beta_{j+1}/\beta_j = (x - j)/(j + 1)(\beta - 1) \]

we obtain

\[ \beta_{r_1}^{\varepsilon x/2} < \beta^x, \quad \beta_{r_2}^{\varepsilon x/2} < \beta^x \]

where

\[ \rho_1 = (x - r_1)/(r_1 + 1)(\beta - 1), \quad \rho_2 = (x - r_2)/(r_2 + 1)(\beta - 1) \]

and where \(\rho_1, \rho_2 > 1\) for \(x\) sufficiently large.

It follows that

\[ \beta_{r_1} < \left(\rho_1^{-\varepsilon/2}\beta\right)^x, \quad \beta_{r_2} < \left(\rho_2^{-\varepsilon/2}\beta\right)^x \]
Proof Of Lemma – \((\varepsilon, 1)\) normality

Hence

\[
\beta \left( \sum_{j < x(1-\varepsilon)/\beta} \beta_j + \sum_{j > x(1+\varepsilon)/\beta} \beta_j \right) < \beta(x + 1) \left[ \beta r_1 + \beta r_2 \right]
\]

\[
< \beta(x + 1) \left[ \left( r_1^{\varepsilon/2} \beta \right)^x + \left( r_2^{\varepsilon/2} \beta \right)^x \right]
\]

\[
< \beta^{\delta(x-1)} \leq N^{\delta}
\]

and the lemma is established for \((\varepsilon, 1)\) normality.
Proof Of Lemma – \((\varepsilon, 1)\) normality

Hence

\[
\beta \left( \sum_{j<x(1-\varepsilon)/\beta} \beta_j + \sum_{j>x(1+\varepsilon)/\beta} \beta_j \right) < \beta(x + 1) \left[ \beta_{r_1} + \beta_{r_2} \right]
\]

\[
< \beta(x + 1) \left[ \left( \rho_1^{-\varepsilon/2} \beta \right)^x + \left( \rho_2^{-\varepsilon/2} \beta \right)^x \right]
\]

\[
< \beta^{\delta(x-1)} \leq N^\delta
\]

and the lemma is established for \((\varepsilon, 1)\) normality.
Proof Of Lemma – \((\varepsilon, 1)\) normality

\[
\beta \left( \sum_{j<x(1-\varepsilon)/\beta} \beta_j + \sum_{j>x(1+\varepsilon)/\beta} \beta_j \right) < \beta(x+1) [\beta r_1 + \beta r_2]
\]

\[
< \beta(x+1) \left[ \left( \rho_1^{-\varepsilon/2} / \beta \right)^x + \left( \rho_2^{-\varepsilon/2} / \beta \right)^x \right]
\]

\[
< \beta^{\delta(x-1)} \leq N^\delta
\]

and the lemma is established for \((\varepsilon, 1)\) normality.
Proof Of Lemma – \((\varepsilon, 1)\) normality

Hence

\[
\beta \left( \sum_{j < x(1-\varepsilon)/\beta} \beta_j + \sum_{j > x(1+\varepsilon)/\beta} \beta_j \right) < \beta(x + 1) \left[ \beta_{r_1} + \beta_{r_2} \right]
\]

\[
< \beta(x + 1) \left[ \left( \frac{\rho_1^{-\varepsilon/2}}{\beta} \right)^x + \left( \frac{\rho_2^{-\varepsilon/2}}{\beta} \right)^x \right]
\]

\[
< \beta^\delta(x - 1) \leq N^\delta
\]

and the lemma is established for \((\varepsilon, 1)\) normality.
Consider the digits $b_0, b_1, \ldots$ of a number $m \leq N$ grouped as follows:

$$b_0, b_1, \ldots, b_{k-1}; b_k, \ldots, b_{2k-1}; b_{2k}, \ldots, b_{3k-1}; \ldots$$

Each of these groups represents a single digit of $m$ when $m$ is expressed in the base $\beta^k$. Hence, there are at most $N^\delta$ integers $m \leq N$ for which the frequency among these groups of a given combination of $k$ digits falls outside the interval from $\beta^{-k} - \varepsilon$ to $\beta^{-k} + \varepsilon$.

The same holds for

$$b_1, b_2, \ldots, b_k; b_{k+1}, \ldots, b_{2k}; \ldots$$

and so on. This gives our result.
Consider the digits $b_0, b_1, \ldots$ of a number $m \leq N$ grouped as follows:

$$b_0, b_1, \ldots, b_{k-1}; b_k, \ldots, b_{2k-1}; b_{2k}, \ldots, b_{3k-1}; \ldots$$

and so on. This gives our result. \qed
Theorem (Copeland-Erdős, 1946)

If \( a_1, a_2, a_3, \ldots \) is an increasing sequence of integers such that for every \( \theta < 1 \) the number of \( a_i \)'s up to \( N \) exceeds \( N^\theta \) provided \( N \) is sufficiently large, then the infinite decimal

\[
0.a_1a_2a_3\ldots
\]

is normal with respect to the base \( \beta \) in which these integers are expressed.
Proof Of Copeland-Erdős Theorem

Consider the numbers $a_1, a_2, \ldots$ of the increasing sequence up to the largest $a_i \leq N$, where $N = \beta^n$. By a counting argument, these numbers altogether have at least $n(1 - \varepsilon) \cdot (N^\theta - N^{1-\varepsilon})$ digits.

Let $f_N$ be the relative frequency of the digit 0. It follows from the lemma that the number of $a_i$'s for which the frequency of the digit 0 exceeds $\beta^{-1} + \varepsilon$ is at most $N^\delta$, and hence

$$f_N < \beta^{-1} + \varepsilon + \frac{nN^\delta}{n(1 - \varepsilon)(N^\theta - N^{1-\varepsilon})}$$

$$= \beta^{-1} + \varepsilon + \frac{N^\delta - \theta}{(1 - \varepsilon)(1 - N^{1-\varepsilon-\theta})}$$
Proof Of Copeland-Erdős Theorem

Consider the numbers $a_1, a_2, \ldots$ of the increasing sequence up to the largest $a_i \leq N$, where $N = \beta^n$. By a counting argument, these numbers altogether have at least $n(1 - \varepsilon) \cdot (N^\theta - N^{1-\varepsilon})$ digits.

Let $f_N$ be the relative frequency of the digit 0. It follows from the lemma that the number of $a_i$'s for which the frequency of the digit 0 exceeds $\beta^{-1} + \varepsilon$ is at most $N^\delta$, and hence

$$f_N < \beta^{-1} + \varepsilon + \frac{nN^\delta}{n(1 - \varepsilon)(N^\theta - N^{1-\varepsilon})}$$

$$= \beta^{-1} + \varepsilon + \frac{N^{\delta-\theta}}{(1 - \varepsilon)(1 - N^{1-\varepsilon-\theta})}$$
Since we are permitted to take $\theta$ greater than $\delta$ and greater than $1 - \varepsilon$, it follows that $\lim_{N \to \infty} f_N$ is at most $\beta^{-1} + \varepsilon$ and hence at most $\beta^{-1}$.

A similar result holds for the digits $1, 2, \ldots, \beta - 1$ and hence each of these digits must have a limiting relative frequency of exactly $\beta^{-1}$.

In a similar manner, it can be shown that the limiting relative frequency of any combination of $k$ digits is $\beta^{-k}$. 

\[ \square \]
Since we are permitted to take $\theta$ greater than $\delta$ and greater than $1 - \varepsilon$, it follows that $\lim_{N \to \infty} f_N$ is at most $\beta^{-1} + \varepsilon$ and hence at most $\beta^{-1}$.

A similar result holds for the digits $1, 2, \ldots, \beta - 1$ and hence each of these digits must have a limiting relative frequency of exactly $\beta^{-1}$.

In a similar manner, it can be shown that the limiting relative frequency of any combination of $k$ digits is $\beta^{-k}$. \qed
Proof Of Copeland-Erdős Theorem

Since we are permitted to take $\theta$ greater than $\delta$ and greater than $1 - \varepsilon$, it follows that $\lim_{N \to \infty} f_N$ is at most $\beta^{-1} + \varepsilon$ and hence at most $\beta^{-1}$.

A similar result holds for the digits $1, 2, \ldots, \beta - 1$ and hence each of these digits must have a limiting relative frequency of exactly $\beta^{-1}$.

In a similar manner, it can be shown that the limiting relative frequency of any combination of $k$ digits is $\beta^{-k}$. \qed
Questions of Strong Normality
A number $\alpha$ is **simply strongly normal** to the base $\beta$, if for each $k \in \{0, 1, \ldots, \beta - 1\}$, we have

$$\limsup_{n \to \infty} \frac{m_k(n) - n/\beta}{\sqrt{2n \log \log n}} = \frac{\sqrt{\beta - 1}}{\beta}$$

and

$$\liminf_{n \to \infty} \frac{m_k(n) - n/\beta}{\sqrt{2n \log \log n}} = -\frac{\sqrt{\beta - 1}}{\beta}$$

where $m_k(n) := \# \{ i : a_i = k, i \leq n \}$.

A number is **strongly normal** to the base $\beta$ if it is simply strongly normal in each base $\beta^j, j = 1, 2, 3, \ldots$, and is **absolutely strongly normal** if it is strongly normal to every base.
**Strong Normality**

**Definition**

A number $\alpha$ is **normal** with respect to the base $\beta$, if for each combination of $k$ digits, $a_1a_2\ldots a_k$, we have

$$\lim_{x \to \infty} \frac{N(x)}{x} = \frac{1}{\beta^k}$$

where $N(x)$ is the number of occurrences of $a_1a_2\ldots a_k$ in the first $x$ digits of $\alpha$.

Some interesting results arising from these definitions are:

- A number which is strongly normal to the base $\beta$ is normal to the base $\beta$.
- Champernowne’s base-$\beta$ number is not strongly normal to the base $\beta$. 

**Strong Normality**

**Definition**

A number $\alpha$ is **normal** with respect to the base $\beta$, if for each combination of $k$ digits, $a_1a_2\ldots a_k$, we have

Jordan Velich

The Theorem of Copeland and Erdős on Normal Numbers
Our Conjecture

Conjecture

The number \( \alpha (= 0.a_1a_2a_3 \ldots ) \) formed from the concatenation of the increasing sequence \( a_1, a_2, a_3, \ldots \) is not strongly normal, provided that the sequence of integers is dense enough, that is, \( N(x) > x^\theta \) for every \( \theta < 1 \) and sufficiently large \( x \).

- **Heuristic:** This conjecture is put forward as a consequence of Champernowne’s number failing to be strongly normal. We believe that all the other concatenation numbers should also fail this strong normality test, the reason being that these sequences are just too dense – there are too few integers being excluded. In this way, we see these concatenation numbers as being basically the same as Champernowne’s number – too structured – and thus we conjecture that these numbers should fail to be strongly normal.
Our Conjecture

Conjecture

The number $\alpha (= 0.a_1a_2a_3 \ldots)$ formed from the concatenation of the increasing sequence $a_1, a_2, a_3, \ldots$ is not strongly normal, provided that the sequence of integers is dense enough, that is, $N(x) > x^\theta$ for every $\theta < 1$ and sufficiently large $x$.

Heuristic: This conjecture is put forward as a consequence of Champernowne’s number failing to be strongly normal. We believe that all the other concatenation numbers should also fail this strong normality test, the reason being that these sequences are just too dense – there are too few integers being excluded. In this way, we see these concatenation numbers as being basically the same as Champernowne’s number – too structured – and thus we conjecture that these numbers should fail to be strongly normal.
Thank you!
